

SRT Export Module Documentation

Purpose

Takes the rich JSON data generated by the transcriber.py module and converts it into a universally readable subtitle format.

Input

transcript.json (Requires a list of dictionaries containing "start", "end", and "text" keys).

Output

output.srt (Standard SubRip file).

Integration

This script can be called by the app.py backend right before the final video is rendered so that the generated .srt file can be burned into the final MP4 using FFmpeg (via the Effects or Render modules).
